Introduction

Background

2.1 Matroid theory

If a mathematical structure can be defined or axiomatized in multiple different, but not obviously equivalent, ways, the different definitions or axiomatizations of that structure make up a cryptomorphism. The many obtusely equivalent definitions of a matroid are a classic example of cryptomorphism, and belie the fact that the matroid is a generalization of concepts in many, seemingly disparate areas of mathematics.

First introduced by Hassler Whitney in 1935 [Whi35], in a seminal paper where he described two axioms for independence in the columns of a matrix, and defined any system obeying these axioms to be a "matroid". Whitney's key insight was that this abstraction of "independence" is applicable to both matrices and graphs. As a result of this, the terms used in matroid theory are borrowed from analogous concepts in both graph theory and linear algebra. Matroids have also been widely studied in game theory and economics, as their properties make them useful for modeling user preferences; for instance, matroid rank functions are a natural way of formally describing course allocation for students [Ben21].

Independent sets

Perhaps the most common way to define a matroid is in terms of its *independent* sets. An independence system is a pair (E, \mathcal{I}) , where E is the ground set of

elements, $E \neq \emptyset$, and \mathcal{I} is the set of independent sets, $\mathcal{I} \subseteq 2^E$. A matroid is an independence system with the following properties:

- 1. The empty set is independent: $\emptyset \in \mathcal{I}$.
- 2. The hereditary property: if $A \subseteq B$ and $B \in \mathcal{I}$, then $A \in \mathcal{I}$.
- 3. The augmentation property: If $A, B \in \mathcal{I}$ and |A| > |B|, then there exists $e \in A$ such that $B \cup \{e\} \in S$.

In practice, the ground set E represents the universe of elements in play, and the independent sets of typically represent the legal combinations of these items. In the context of fair allocation, the independent sets represent the legal (in the case of matroid constraints) or desired (in the case of matroid utilities) bundles of items.

Rank

Given a matroid $\mathfrak{M}=(E,\mathcal{I})$, the matroid rank function (MRF) is a function rank: $2^E \to \mathbb{Z}^+$ that gives the rank of a set $A \subseteq E$, which is defined to be the size of the largest independent subset of A. Formally,

$$rank(A) = max\{|X| : X \subseteq A \text{ and } X \in \mathcal{I}\}.$$

Matroid rank functions are binary submodular. Binary because they have binary marginals, that is, $\operatorname{rank}(A \cup \{e\}) - \operatorname{rank}(A) \in \{0,1\}$, for all $A \subseteq 2^E$ and $e \in E$. Submodularity refers to rank functions' natural diminishing returns property, namely that for any two sets $X, Y \subseteq E$, we have

$$\operatorname{rank}(X \cup Y) + \operatorname{rank}(X \cap Y) \le \operatorname{rank}(X) + \operatorname{rank}(Y).$$

This diminishing returns property makes the rank function useful for modeling user preferences, and is a reason why matroids show up so often in economics and game theory (???).

Closed sets

We also need to establish the concept of the *closed sets* of a matroid. A closed set is a set whose cardinality is maximal for its rank. Equivalently to the definition given above, we can define a matroid as $\mathfrak{M} = (E, \mathcal{F})$, where \mathcal{F} is the set of closed sets of \mathfrak{M} , satisfying the following properties:

1	The set	of all	elements	ic	closed.	$E \subset \mathcal{F}$	•
т.	THE SEC	or an	elements	15	CIOSEG.	12/	

- 2. The intersection of two closed sets is a closed set: If $A,B\in\mathcal{F},$ then $A\cap B\in\mathcal{F}$
- 3. If $A \in \mathcal{F}$ and $a, b \in E \setminus A$, then b is a member of all sets in \mathcal{F} containing $A \cup \{a\}$ if and only if a is a member of all sets in \mathcal{F} containing $A \cup \{b\}$

Random matroid generation

One goal for this project is to create the Julia library Matroids.jl, which will supply functionality for generating and interacting with random matroids. In the preparatory project delivered fall of 2022, I implemented Knuth's 1974 algorithm for the random generation of arbitrary matroids via the erection of closed sets [Knu75]. With this, I was able to randomly generate matroids with a universe size n of about 12, but for larger values of n my implementation was unbearably slow. In this chapter, Knuth's method for random matroid construction will be described, along with the steps I have taken to speed up my initial, naïve implementation. The random generation of other specific types of matroids is discussed as well.

3.1 Knuth's matroid construction (KMC)

KNUTH-MATROID (given in Algorithm 1) accepts the ground set E and a list of enlargements X, and produces the matroid over E where each set in X[r] is a closed set of rank r. The output is the list $F = [F_0, \ldots, F_r]$, where r is the final rank of \mathfrak{M} and F_i is the set of closed sets of rank i. In the paper, Knuth shows that $\bigcup_{i=0}^{r} F[r] = \mathcal{F}$, and so the resulting structure $\mathfrak{M} = (E, \mathcal{F})$ is a matroid.

The algorithm proceeds in a bottom-up manner, starting with the single closed set of rank 0 (the empty set) and for each rank r + 1 adds the covers of the closed sets of rank r. The covers of a closed set A of rank r is simply all sets obtained by adding one more element from E to A. The covers are generated with the helper method Generate-Covers(F, r, E).

```
GENERATE-COVERS(F, r, E)
1 return \{A \cup \{a\} : A \in F[r], a \in E \setminus A\}
```

Given no enlargements (X = []), the resulting matroid is the uniform matroid of rank |E|. Arbitrary matroids can be generated by supplying different lists X. When enlarging, the sets in X[r+1] are simply added to F[r+1].

SUPERPOSE!(F[r+1], F[r]) ensures that the newly enlarged set of closed sets of rank r+1 is valid. If F_{r+1} contains two sets A, B whose intersection $A \cap B \not\subseteq C$, for some $C \in F_r$, replace A, B with $A \cup B$. Repeat until no two sets exist in F_{r+1} whose intersection is not contained within some set $C \in F_r$.

```
Superpose!(F_{r+1}, F_r)
     for A \in F_{r+1}
 2
            for B \in F_{r+1}
                   flag \leftarrow true
 3
                   for C \in F_r
 4
 5
                         if A \cap B \subseteq C
 6
                                flag \leftarrow false
 7
 8
                   if flag = true
                         F_{r+1} \leftarrow F_{r+1} \setminus \{A, B\}
 9
                         F_{r+1} \leftarrow F_{r+1} \cup \{A \cup B\}
10
```

3.1.1 Randomized KMC

In the randomized version of KNUTH-MATROID, we generate matroids by applying a supplied number of random coarsening steps, instead of enlarging with supplied sets. This is done by applying SUPERPOSE! immediately after adding the covers, then choosing a random member A of F[r+1] and a random element $a \in E \setminus A$, replacing A with $A \cup \{a\}$ and finally reapplying SUPERPOSE!. The parameter $p = (p_1, p_2, \ldots)$ gives the number of such coarsening steps to be applied at each iteration of the algorithm.

The pseudocode given up to this point corresponds closely to the initial Julia implementation, which can be found in Appendix A.1. It should already be clear that this brute force implementation leads to poor performance – for instance, the Superpose! method uses a triply nested for loop, which is a candidate

```
Algorithm 1 KNUTH-MATROID(E, X)
Input:
             The ground set of elements E, and a list of enlargements X.
Output:
             The list of closed sets of the resulting matroid grouped by rank,
             F = [F_0, \dots, F_r], where F_i is the set of closed sets of rank i.
1 r = 0, F = [\{\emptyset\}]
   while true
2
3
       Push!(F, Generate-Covers(F, r, E))
       F[r+1] = F[r+1] \cup X[r+1]
4
       Superpose!(F[r+1], F[r])
5
       if E \not\in F[r+1]
6
            r \leftarrow r + 1
7
       else
8
9
            return (E, F)
```

for significant improvement if possible. Section 3.1.2 describes the engineering work done to create a more performant implementation.

3.1.2 Improving performance

When recreating Knuth's table of observed mean values for the randomly generated matroids, some of the latter configurations of n and $(p_1, p_2, ...)$ was unworkably slow, presumably due to the naïve implementation of the algorithm. Table 3.1 shows the performance of this first implementation.

The performance was measured using Julia's $@timed^1$ macro, which returns the time it takes to execute a function call, how much of that time was spent in garbage collection and the size of the memory allocated. As is evident from the data, larger matroids are computationally quite demanding to compute with the current approach, and the time and space requirements scales exponentially with n. Can we do better? As it turns out, we can; after the improvements outlined in this section, we will be able to generate matroids over universes as large as n = 128 in a manner of seconds and megabytes.

¹https://docs.julialang.org/en/v1/base/base/#Base.@timed

```
Algorithm 2 Randomized-Knuth-Matroid(E, p)
Input:
             The ground set of elements E, and a list p = [p_1, p_2, ...], where
             p_r is the number of coarsening steps to apply at rank r in the
             construction.
Output:
             The list of closed sets of the resulting matroid grouped by rank,
             F = [F_0, \dots, F_r], where F_i is the set of closed sets of rank i.
 1 r = 0, F = [\{\emptyset\}]
   while true
 2
        Push!(F, Generate-Covers(F, r, E))
 3
        Superpose!(F[r+1], F[r])
 4
        if E \in F[r+1] return (E, F)
 5
        while p[r] > 0
 6
             let A be a random set in F[r+1]
 7
             let a be a random element in E \setminus A
 8
             replace A with A \cup \{a\} in F[r+1]
 9
             Superpose!(F[r+1], F[r])
10
             if E \in F[r+1] return (E,F)
11
             p[r] - = 1
12
13
        r+=1
```

Representing sets as binary numbers

The first improvement we will attempt is to represent our families as sets of hexadecimal numbers, instead of sets of sets of numbers. Sets are represented using Julia's native Set type 2 . The Julia implementation at this point can be found in Appendix A.2.

 $^{^2} https://docs.julialang.org/en/v1/base/collections/\#Base.Set$

10	(0, 4, 2)	100	0.1924601	0.0284532	$406.131~\mathrm{MiB}$
10	(0, 3, 3)	100	0.3196838	0.0463972	$678.206~\mathrm{MiB}$
10	(0, 0, 6)	100	1.1420602	0.1671325	$2.356~\mathrm{GiB}$
10	(0, 1, 1, 1)	100	2.9283978	0.3569357	$5.250~\mathrm{GiB}$
13	(0, 6, 0)	10	104.0171128	9.9214449	$161.523~\mathrm{GiB}$
13	(0, 6, 2)	10	11.4881308	1.3777947	$20.888~\mathrm{GiB}$
16	(6, 0, 0)	1	-	-	-

The idea is to define a family of closed sets of the same rank as $Set{UInt16}$. Using UInt16 we can support ground sets of size up to 16. Each 16-bit number represents a set in the family. For instance, the set $\{2,5,7\}$ is represented by

$$164 = 0 \times 00 = 4 = 0 \times 000000000010100100 = 2^7 + 2^5 + 2^2.$$

At either end we have $\emptyset \equiv 0$ x0000 and $E \equiv 0$ xffff (if n = 16). Set operations have equivalent binary operations; intersection corresponds to bitwise AND, union to bitwise OR and the set difference between sets A and B to the bitwise OR of A and the complement of B. Subset equality is also simple to implement: $A \subseteq B \iff A \cap B = A$.

We can now describe the bitwise versions of the required methods. The bitwise implementation of Generate-Covers finds all elements in $E \setminus A$ by finding each value i for which $A \in 1 << i === 0$, meaning that the set represented by 1 << i is not a subset of A. The bitwise implementation of Superpose! is unchanged apart from using the bitwise set operations described above.

The performance of random_kmc_v2 is shown in Table 3.2. It is clear that representing closed sets using binary numbers represents a substantial im-

16	[0, 6, 0]	10	1.2102877	0.0146129	$450.052~\mathrm{MiB}$

provement – we are looking at performance increases of 100x-1000x across the board.

Sorted superpose

Can we improve the running time of the algorithm further? It is clear that SUPERPOSE! takes up a large portion of the compute time. In the worst case, when no enlargements have been made, F_{r+1} is the set of all r+1-sized subsets of E, $|F_{r+1}| = \binom{n}{r+1}$. Comparing each $A, B \in F_{r+1}$ with each $C \in F_r$ in a triply nested for loop requires a whopping $\mathcal{O}(\binom{n}{r+1}^2\binom{n}{r})$ operations. In the worst case, no enlargements are made at all, and we build the free matroid in $\mathcal{O}(2^{3n})$ time.

Observing the step-by-step calls to Superpose!, we see that there are a lot of duplicate and unnecessary sets being processed. The duplicate sets stem from Generate-Covers, whose current implementation does not take into account that any two sets of rank r will have at least one cover in common. To see this, consider a matroid-under-construction where $A = \{1,2\}$ and $B = \{1,3\}$ are closed sets of rank 2. Currently, Generate-Covers will happily generate the cover $C = \{1,2,3\}$ twice, once as the cover of A and subsequently as the cover of B. Non-redundant cover generation was a worthwhile improvement and is described below.

After larger closed sets have been added to F[r+1], SUPERPOSE! will cause sets to merge, so that only maximal dependent sets remain. Some sets will even simply disappear. In the case where $X = \{1,2\}$ was added by GENERATE-COVERS, and the $Y = \{1,2,3\}$ was added manually as an enlargement, the smaller set will be completely subsumed in the bigger set, as $\{1,2\} \cap \{1,2,3\} = \{1,2\}$ and $\{1,2\} \cup \{1,2,3\} = \{1,2,3\}$. In this situation, X will "eat" the covers $\{1,3\}$ and $\{2,3\}$ as well. Since the larger sets will absorb so many of the smaller sets (around $\binom{p}{r+1}$), where p is the size of the larger set and r+1 is the size of the smallest sets allowed to be added in a given iteration), might it be an idea to perform the superpose operation in descending order based on the size of the sets? This should result in fewer calls to SUPERPOSE!, as the bigger sets will remove the smaller sets that fully overlap with them in the early iterations, however, the repeated sorting of the sets might negate this performance gain. This was the idea behind random_kmc_v3, which can be found in Appendix A.2.

Unfortunately, as Table 3.3 shows, this implementation is a few times slower and more space demanding than the previous implementation. This is likely due to the fact that an ordered list is more space inefficient than the hashmap-based Set.

Table 3.3: Performance of random_kmc_v3.

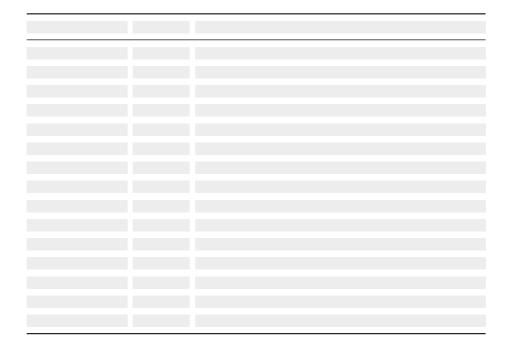

\overline{n}	(p_1,p_2,\ldots)	Trials	Time	GC Time	Bytes allocated

13	[0, 6, 2]	10	0.0106478	0.0007704	$20.774~\mathrm{MiB}$
16	[0, 6, 0]	10	0.6070136	0.0095656	$310.183~\mathrm{MiB}$

Iterative superpose

So far, we are inserting all covers of F_r into F_{r+1} along with all enlargements, and then running the superpose operation on all of them at once. Until this point, the superpose operation was performed with a triply nested for loop, c Thus we were looking at a whopping to perform the superpose part of step r.

A library for fair allocation with matroids

A goal for this project is to introduce Matroids. JI as a useful library for experimenting with fair allocation that require matroids. In the previous chapter, we explored how this library generates random matroids, however this is not very useful until we also have in place an API layer to allow fair allocation algorithms to interface with our matroids in a practical and efficient manner.

4.1	The matroid uni	on algorithm	

4.2 Supporting universe sizes of n > 128

The larger the ground set, the closer we are to an instance of The cake-cutting problem. Typical fair allocation problems with indivisible items deal with less

than 100 items.

In other words, the Integer cap of 128 bits is a reasonable upper limit on universe size for fair allocation problems. However, one could look into using packages that add larger fixed-width integer types¹. Matroids.jl supports arbitrary integer types.

¹See for instance BitIntegers.jl

Fair allocation with matroid rank utilities

We wish to study fair allocation in which the utility function of each agent is a matroid rank function. That is, the utility function for each agent $i \in [n]$ is the rank function for a matroid $\mathfrak{M}_i = ([m], \mathcal{I}_i)$.

$$S_i \in \mathcal{I}_i \iff v_i(S_i) = |S_i|.$$

 If F_{r+1} contains any two sets A, B whose intersection A \cap B is not
      contained in C for any C \in F_r, replace A, B \in F_{r+1} by the single set
      A \cup B. Repeat this operation until A \cap B \subseteq C for some C \in F_r whenever A
      and B are distinct members of F_{r+1}.
 F and F_old should be Family: A Set of Sets of some type.
 This is the first, Set-based implementation of this method.
function superpose_v1!(F, F_old)
 for A \in F
   for B ∈ F
      should_merge = true
     for C ∈ F_old
       if A \cap B \subseteq C
         should_merge = false
       end
      end
```

```
if should_merge
        setdiff!(F, [A, B])
         push! (F, A \cup B)
      end
    end
  end
 return F
end
....
First implementation of Knuth's random matroid construction through random "
    coarsening".
n is the size of the universe.
p is a list (p_1, p_2, ...), where p_r is the number of coarsening steps to apply at rank r in the construction. The first entry of p should usually be
      0, since adding closed sets of size > 1 at rank 1 is equivalent to
     shrinking E.
This uses the Set-based KMC methods.
function random_kmc_v1(n, p, T)::KnuthMatroid{Set{Integer}}
 E = Set([i for i in range(0, n-1)])
  # Step 1: Initialize.
 r = 1
  F = [family([])]
  pr = 0
  while true
    # Step 2: Generate covers.
    push!(F, generate_covers_v1(F[r], E))
    # Step 4: Superpose.
    superpose_v1!(F[r+1], F[r])
    # Step 5: Test for completion.
    \textbf{if} \ \mathbb{E} \ \in \ \mathbb{F} \, [\, r \! + \! 1 \, ]
     return KnuthMatroid{Set{Integer}}(n, F, [], Set(), Dict())
    end
    if r <= length(p)</pre>
     pr = p[r]
    end
    while pr > 0
      # Random closed set in F_{r+1} and element in E \setminus A.
      A = rand(F[r+1])
      a = rand(setdiff(E, A))
       \# Replace A with A \cup {a}.
      F[r+1] = setdiff(F[r+1], A) \cup Set([A \cup a])
       # Superpose again to account for coarsening step.
       superpose_v1!(F[r+1], F[r])
```

```
# Step 5: Test for completion.
if E ∈ F[r+1]
    return KnuthMatroid{Set{Integer}}(n, F, [], Set(), Dict())
end

pr -= 1
end

r += 1
end
end
```

A.2 random_kmc_v2 and random_kmc_v3

```
Generate the set F_{r+1} of all "covers" of the sets in F_r, given the size of
   the universe. Bit-based.
function generate_covers_v2(F_r, n)
 Set([A | 1 << i for A \in F_r for i in 0:n-1 if A & 1 << i === 0])
end
Returns whether the intersection of A and B is contained within
some C in F_prev.
function should_merge(A, B, F_prev)
 for C in F_prev
   if subseteq(A & B, C)
     return false
 end
 return true
end
If F contains any two sets A, B whose intersection A \cap B is not contained in C
    for any C \in F_prev, replace A, B \in F with the single set A \cup B. Repeat this
     operation until A \cap B \subseteq C for some C \in F_prev whenever A and B are
    distinct members of F.
This implementation represents the sets using bits.
function bitwise_superpose! (F, F_prev)
 As = copy(F)
 while length(As) !== 0
   A = pop!(As)
 for B in setdiff(F, A)
```

```
if should_merge(A, B, F_prev)
        push!(As, A | B)
        setdiff!(F, [A, B])
        push! (F, A | B)
        break
      end
    end
  end
  return F
end
function sorted_bitwise_superpose!(F, F_prev)
 As = sort!(collect(F), by = s -> length(bits_to_set(s)))
 while length(As) !== 0
   A = popfirst!(As)
    for B in setdiff(F, A)
      if should_merge(A, B, F_prev)
        insert! (As, 1, A | B) setdiff! (F, [A, B]) push! (F, A | B)
        break
      end
   end
 end
 return F
end
Bitwise implementation of Knuth's approach to random matroid generation through
    a number of random "coarsening" steps. Supply the generate_covers and superpose methods to study the effects of different implementations of
     these.
n is the size of the universe.
p is a list (p_1, p_2, \dots), where p_r is the number of coarsening steps to
     apply at rank r in the construction. The first entry of p should usually be
      0, since adding closed sets of size > 1 at rank 1 is equivalent to
     shrinking E.
function random_bitwise_kmc(generate_covers, superpose, n, p)::KnuthMatroid{Any}
# Initialize.
 r = 1
 pr = 0
 F = [Set(0)]
 E = 2^n - 1 # The set of all elements in E.
 while true
    # Generate covers.
    push!(F, generate_covers(F[r], n))
    # Superpose.
    superpose (F[r+1], F[r])
    # Test for completion.
    if E ∈ F[r+1]
```

```
return KnuthMatroid{Any}(n, F, [], Set(), Dict())
    end
    # Apply coarsening.
if r <= length(p)</pre>
     pr = p[r]
    end
    while pr > 0
      \# Get random closed set A in F_{r+1} and element a in E - A.
      A = rand(F[r+1])
      a = random_element(diff(E, A))
      # Replace A with A U {a}.
     F[r+1] = setdiff(F[r+1], A) \cup Set([A | a])
      # Superpose again to account for coarsening step.
      superpose(F[r+1], F[r])
      # Step 5: Test for completion.
      \textbf{if} \ E \ \in \ F\,[\,r+1\,]
       return KnuthMatroid{Any}(n, F, [], Set(), Dict())
      end
     pr -= 1
    end
    r += 1
  end
end
Second implementation of random-KMC. This uses the bit-based KMC methods.
function random_kmc_v2(n, p, T=UInt16)
 return random_bitwise_kmc(generate_covers_v2, bitwise_superpose!, n, p)
end
Third implementation of random-KMC. This sorts the sets by size before
    superposing.
function random_kmc_v3(n, p, T=UInt16)
return random_bitwise_kmc(generate_covers_v2, sorted_bitwise_superpose!, n, p)
end
```

A.3 random_kmc_v4

```
This is an attempt at a smarter implementation than directly following the setup from Knuth's 1974 article. The superpose step is replaced by an insert
```

```
operation that inserts new closed sets into the family of current rank one
              at a time, superposing on the fly.
\textbf{function} \ \texttt{randomized\_knuth\_matroid\_construction\_v4} \ (\texttt{n, p, T=UInt16}):: \texttt{KnuthMatroid} \{ \texttt{knuthMatroid} \} \ \texttt{KnuthMatroid} \} \ \texttt{Matroid} = \texttt{Matroid\_knuth\_matroid\_construction\_v4} \ \texttt{Matroid\_knuth\_matroid\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construction\_construct
      r = 1
     pr = 0

                    return KnuthMatroid{T}(n, F, [], Set(), Dict())
               end
             r += 1
      end
```

A.4 random_kmc_v5

```
ппп
```

```
Fifth implementation of random-KMC. This one uses a dictionary to keep track of
previously seen sets.
function random_kmc_v5(n, p, T=UInt16)::KnuthMatroid{T}
 r = 1
  pr = 0
  F::Vector{Set{T}} = [Set(T(0))]
  rank = Dict{T, UInt8}(0=>0) # The rank table maps from the representation of a
       set to its assigned rank.
  while true
    to_insert = generate_covers_v2(F[r], n)
    # Apply coarsening to covers.
    if r <= length(p)</pre>
      pr = p[r]
      while length(to_insert) > 0 && pr > 0 && E \notin to_insert \# No need to
          coarsen if E is added.
        A = rand(to_insert)
        a = random_element(E - A)
        to_insert = setdiff(to_insert, A) U [A | a]
        pr -= 1
      end
    end
    # Superpose.
    push!(F, Set()) # Add F[r+1].
    while length(to_insert) > 0
      A = pop!(to_insert)
      push! (F[r+1], A)
      rank[A] = r
      for B in setdiff(F[r+1], A)
        if !haskey(rank, A&B) || rank[A&B] >= r
          # Update insert queue.
          push! (to_insert, A | B)
          # Update F[r+1].
setdiff!(F[r+1], [A, B])
          push! (F[r+1], A | B)
          # Update rank table.
          rank[A|B] = r
          break
        end
      end
    end
    \textbf{if} \ \texttt{E} \ \in \ \texttt{F[r+1]}
     return KnuthMatroid{T}(n, F, [], Set(), rank)
    end
    r += 1
  end
end
```

A.5 random_kmc_v6

```
Sixth implementation of random-KMC, in which a rank table is used to keep track
     of set ranks, and the covers and enlargements are added one at a time,
     ensuring the matroid properties at all times.
function random_kmc_v6(n, p, T=UInt16)::KnuthMatroid{T}
 pr = 0
 F::Vector{Set{T}} = [Set(T(0))]
 E::T = BigInt(2)^n-1
  rank = Dict\{T, UInt8\}(0=>0)
  while E ∉ F[r]
   # Create empty set.
push!(F, Set())
    \# Generate minimal closed sets for rank r+1.
    for y in F[r] # y is a closed set of rank r.
     t = E - y \# The set of elements not in y.

\# Find all sets in F[r+1] that already contain y and remove excess
           elements from t.
      for x in F[r+1]
        if (x & y == y) t &= ~x end
      \# Insert y \cup a for all a \in t.
      while t > 0
        x = y | (t&-t)
        add_set!(x, F, r, rank)
      end
    end
    \textbf{if} \ \mathbb{E} \ \in \ \mathbb{F} \, [\, \texttt{r+1} \, ]
      break
    end
    if r <= length(p)</pre>
      # Apply coarsening.
      pr = p[r]
      while pr > 0 \&\& E \notin F[r+1]
        A = rand(F[r+1])
         t = E-A
        one_element_added::Vector{T} = []
        while t > 0
          x = A | (t&-t)
          push! (one_element_added, x)
           t &= ~x
        Acupa = rand(one_element_added)
        setdiff!(F[r+1], A)
        add_set!(Acupa, F, r, rank)
        pr -= 1
      end
```

```
end
    r += 1
end

return KnuthMatroid{T}(n, F, [], Set(), rank)
end

function add_set!(x, F, r, rank)
    if x in F[r+1] return end
    for y in F[r+1]
    if haskey(rank, x&y) && rank[x&y]<r
        continue
    end

# x \cap y has rank > r, replace with x \cup y.
    setdiff!(F[r+1], y)
    return add_set!(x|y, F, r, rank)
end

push!(F[r+1], x)
    rank[x] = r
end
```
